python%2F&title=Vector%20Autoregression%20(VAR)%20%E2%80%93%20Comprehensive%20Guide%20With%20Fx3mpless%20in%20Python)

Vector Autoregression (VAR) is a forecasting algorithm that can be used when two or more time series influence each other. That is, the relationship between the time series involved is bi-directional. In this post, we will see the concepts, intuition behind VAR models and see a comprehensive and correct method to train and forecast VAR models in python using statsmodels.

## 1. Introduction

First, what is Vector Autoregression (VAR) and when to use it?

Vector Autoregression (VAR) is a multivariate forecasting algorithm that is used when two or more <u>time series(https://www.machinelearningplus.com/time-series/time-series-analysis-python/)</u> influence each other.

That means, the basic requirements in order to use VAR are:

- 1. You need at least two time series (variables)
- 2. The time series should influence each other.

Alright. So why is it called 'Autoregressive'?

It is considered as an Autoregressive model because, each variable (Time Series) is modeled as a function of the past values, that is the predictors are nothing but the lags (time delayed value) of the series.

Ok, so how is VAR different from other Autoregressive models like AR, ARMA or ARIMA?

The primary difference is those models are uni-directional, where, the predictors influence the Y and not vice-versa. Whereas, Vector Auto Regression (VAR) is bi-directional. That is, the variables influence each other.

We will go more in detail in the next section.

In this article you will gain a clear understanding of:

- · Intuition behind VAR Model formula
- How to check the bi-directional relationship using Granger Causality
- Procedure to building a VAR model in Python
- How to determine the right order of VAR model
- Interpreting the results of VAR model

future.

• How to generate forecasts to original scale of time series

## 2. Intuition behind VAR Model Formula

If you remember in <u>Autoregression models</u> (<a href="https://www.machinelearningplus.com/time-series/arima-model-time-series-forecasting-python/">https://www.machinelearningplus.com/time-series/arima-model-time-series-forecasting-python/</a>), the time series is modeled as a linear combination of it's own lags. That is, the past values of the series are used to forecast the current and

A typical AR(p) model equation looks something like this:

(https://www.machinelearningplus.com/wp-content/uploads/2019/07/Equation ARp Model-min.png)

where  $\alpha$  is the intercept, a constant and  $\beta 1,~\beta 2$  till  $\beta p$  are the coefficients of the lags of Y till order p.

Order 'p' means, up to p-lags of Y is used and they are the predictors in the equation. The  $\epsilon_{t}$  is the error, which is considered as white noise.

Alright. So, how does a VAR model's formula look like?

In the VAR model, each variable is modeled as a **linear combination of past values of itself and the past values of other variables in the system** Since you have multiple time series that influence each other, it is modeled as a system of equations with one equation per variable (time series).

That is, if you have 5 time series that influence each other, we will have a system of 5 equations.

Well, how is the equation exactly framed?

Let's suppose, you have two variables (Time series) Y1 and Y2, and you need to forecast the values of these variables at time (t).

To calculate Y1(t), VAR will use the past values of both Y1 as well as Y2. Likewise, to compute Y2(t), the past values of both Y1 and Y2 be used.

For example, the system of equations for a VAR(1) model with two time series (variables 'Y1' and 'Y2') is as follows:

(https://www.machinelearningplus.com/wp-content/uploads/2019/07/Equation VAR1 Model-min.png).

Where, Y{1,t-1} and Y{2,t-1} are the first lag of time series Y1 and Y2 respectively.

The above equation is referred to as a VAR(1) model, because, each equation is of order 1, that is, it contains up to one lag of each of the predictors (Y1 and Y2).

Since the Y terms in the equations are interrelated, the Y's are considered as endogenous variables, rather than as exogenous predictors.

Likewise, the second order VAR(2) model for two variables would include up to two lags for each variable (Y1 and Y2).

(https://www.machinelearningplus.com/wpcontent/uploads/2019/07/Equation\_VAR2\_Model-min.png)

Can you imagine what a second order VAR(2) model with three variables (Y1, Y2 and Y3) would look like?

(https://www.machinelearningplus.com/wpcontent/uploads/2019/07/Equation VAR2 Model with three Ys-min.png)

As you increase the number of time series (variables) in the model the system of equations become larger.

# 3. Building a VAR model in Python

The procedure to build a VAR model involves the following steps:

- 1. Analyze the time series characteristics
- 2. Test for causation amongst the time series

# 4. Import the datasets

For this article let's use the time series used in Yash P Mehra's 1994 article: "Wage Growth and the Inflation Process: An Empirical Approach".

This dataset has the following 8 quarterly time series:

1. rgnp: Real GNP.

2. pgnp: Potential real GNP.

3. ulc : Unit labor cost.

**4.** gdfco : **Fixed** weight deflator **for** personal consumption expenditure excluding food **and** energy.

5. gdf : Fixed weight GNP deflator.

6. gdfim: Fixed weight import deflator.

7. gdfcf : **Fixed** weight deflator **for** food **in** personal consumption expenditure.

8. gdfce: Fixed weight deflator for energy in personal consumption expenditure.

Let's import the data.

 $filepath = "\c https://raw.githubusercontent.com/selva86/datasets/master/Raotbl6.csv\_(https://raw.githubusercontent.com/selva86/datasets/master/Raotbl6.csv\_(https://raw.githubusercontent.com/selva86/datasets/master/Raotbl6.csv\_(https://raw.githubusercontent.com/selva86/datasets/master/Raotbl6.csv\_(https://raw.githubusercontent.com/selva86/datasets/master/Raotbl6.csv\_(https://raw.githubusercontent.com/selva86/datasets/master/Raotbl6.csv\_(https://raw.githubusercontent.com/selva86/datasets/master/Raotbl6.csv\_(https://raw.githubusercontent.com/selva86/datasets/master/Raotbl6.csv\_(https://raw.githubusercontent.com/selva86/datasets/master/Raotbl6.csv\_(https://raw.githubusercontent.com/selva86/datasets/master/Raotbl6.csv\_(https://raw.githubusercontent.com/selva86/datasets/master/Raotbl6.csv\_(https://raw.githubusercontent.com/selva86/datasets/master/Raotbl6.csv\_(https://raw.githubusercontent.com/selva86/datasets/master/Raotbl6.csv\_(https://raw.githubusercontent.com/selva86/datasets/master/Raotbl6.csv\_(https://raw.githubusercontent.com/selva86/datasets/master/Raotbl6.csv\_(https://raw.githubusercontent.com/selva86/datasets/master/Raotbl6.csv\_(https://raw.githubusercontent.com/selva86/datasets/master/Raotbl6.csv\_(https://raw.githubusercontent.com/selva86/datasets/master/Raotbl6.csv\_(https://raw.githubusercontent.com/selva86/datasets/master/Raotbl6.csv\_(https://raw.githubusercontent.com/selva86/datasets/master/Raotbl6.csv\_(https://raw.githubusercontent.com/selva86/datasets/master/Raotbl6.csv\_(https://raw.githubusercontent.com/selva86/datasets/master/Raotbl6.csv\_(https://raw.githubusercontent.com/selva86/datasets/master/Raotbl6.csv\_(https://raw.githubusercontent.com/selva86/datasets/master/Raotbl6.csv\_(https://raw.githubusercontent.com/selva86/datasets/master/Raotbl6.csv\_(https://raw.githubusercontent.com/selva86/datasets/master/Raotbl6.csv\_(https://raw.githubusercontent.com/selva86/datasets/master/Raotbl6.csv\_(https://raw.githubusercontent.com/selva86/datasets/master/Raotbl6.csv\_(https://raw.githubusercontent.com/selva86$

Actual Multi Dimensional Time Series for VAR model

Each of the series have a fairly similar trend patterns over the years except for gdfce and gdfim, where a different pattern is noticed starting in 1980.

Alright, next step in the analysis is to check for causality amongst these series. The Granger's Causality test and the Cointegration test can help us with that.

# 6. Testing Causation using Granger's Causality **Test**

The basis behind Vector AutoRegression is that each of the time series in the system influences each other. That is, you can predict the series with past values of itself along with other series in the system.

Using Granger's Causality Test, it's possible to test this relationship before even building the model.

So what does Granger's Causality really test?

Granger's causality tests the null hypothesis that the coefficients of past values in the regression equation is zero.

In simpler terms, the past values of time series (X) do not cause the other series (Y). So, if the p-value obtained from the test is lesser than the significance level of 0.05, then, you can safely reject the null hypothesis.

The below code implements the Granger's Causality test for all possible combinations of the time series in a given dataframe and stores the p-values of each combination in the output matrix.

```
from statsmodels.tsa.stattools import grangercausalitytests
maxlag=12
test = 'ssr_chi2test'
def grangers_causation_matrix(data, variables, test='ssr_chi2test', verbose=False):
  """Check Granger Causality of all possible combinations of the Time series.
  The rows are the response variable, columns are predictors. The values in the table
  are the P-Values. P-Values lesser than the significance level (0.05), implies
  the Null Hypothesis that the coefficients of the corresponding past values is
  zero, that is, the X does not cause Y can be rejected.
        : pandas dataframe containing the time series variables
  variables: list containing names of the time series variables.
  df = pd.DataFrame(np.zeros((len(variables), len(variables))), columns=variables, index=variables)
  for c in df.columns:
    for r in df.index:
       test_result = grangercausalitytests(data[[r, c]], maxlag=maxlag, verbose=False)
       p_values = [round(test_result[i+1][0][test][1],4) for i in range(maxlag)]
       if verbose: print(f'Y = \{r\}, X = \{c\}, P Values = \{p\_values\}')
       min_p_value = np.min(p_values)
       df.loc[r, c] = min_p_value
  df.columns = [var + '_x' for var in variables]
  df.index = [var + '_y' for var in variables]
  return df
grangers_causation_matrix(df, variables = df.columns)
```

So how to read the above output?

The row are the Response (Y) and the columns are the predictor series (X).

For example, if you take the value 0.0003 in (row 1, column 2), it refers to the p-value of pgnp\_x causing rgnp\_y. Whereas, the 0.000 in (row 2, column 1) refers to the p-value of rgnp\_y causing pgnp\_x.

So, how to interpret the p-values?

If a given p-value is < significance level (0.05), then, the corresponding X series (column) causes the Y (row).

For example, P-Value of 0.0003 at (row 1, column 2) represents the p-value of the Grangers Causality test for pgnp\_x causing rgnp\_y, which is less that the significance level of 0.05.

So, you can reject the null hypothesis and conclude pgnp\_x causes rgnp\_y.

Looking at the P-Values in the above table, you can pretty much observe that all the variables (time series) in the system are interchangeably causing each other.

This makes this system of multi time series a good candidate for using VAR models to forecast.

Next, let's do the Cointegration test.

# 7. Cointegration Test

Cointegration test helps to establish the presence of a statistically significant connection between two or more time series.

But, what does Cointegration mean?

To understand that, you first need to know what is 'order of integration' (d).

Order of integration(d) is nothing but the number of differencing required to make a non-stationary time series stationary.

Now, when you have two or more time series, and there exists a linear combination of them that has an order of integration (d) less than that of the individual series, then the collection of series is said to be cointegrated.

Ok?

When two or more time series are cointegrated, it means they have a long run, statistically significant relationship.

This is the basic premise on which Vector Autoregression(VAR) models is based on. So, it's fairly common to implement the cointegration test before starting to build VAR models.

Alright, So how to do this test?

Soren Johanssen in his paper (1991) (https://www.jstor.org/stable/2938278?  $seq=1\#page\_sean\_tab\_contents$ ) devised a procedure to implement the cointegration test.

It is fairly straightforward to implement in python's statsmodels, as you can see below.

```
from statsmodels.tsa.vector_ar.vecm import coint_johansen

def cointegration_test(df, alpha=0.05):
    """Perform Johanson's Cointegration Test and Report Summary"""
    out = coint_johansen(df,-1,5)
    d = {'0.90':0, '0.95':1, '0.99':2}
    traces = out.lr1
    cvts = out.cvt[:, d[str(1-alpha)]]
    def adjust(val, length= 6): return str(val).ljust(length)

# Summary
    print('Name :: Test Stat > C(95%) => Signif \n', '--'*20)
    for col, trace, cvt in zip(df.columns, traces, cvts):
        print(adjust(col), ':: ', adjust(round(trace,2), 9), ">", adjust(cvt, 8), ' => ', trace > cvt)

cointegration_test(df)
```

Results:

# 8. Split the Series into Training and Testing Data

Splitting the dataset into training and test data.

The VAR model will be fitted on df\_train and then used to forecast the next 4 observations. These forecasts will be compared against the actuals present in test data

To do the comparisons, we will use multiple forecast accuracy metrics, as seen later in this article.

```
nobs = 4

df_train, df_test = df[0:-nobs], df[-nobs:]

# Check size

print(df_train.shape) # (119, 8)

print(df_test.shape) # (4, 8)
```

Since the VAR model requires the time series you want to forecast to be stationary,

# 9. Check for Stationarity and Make the Time Series Stationary

it is customary to check all the time series in the system for stationarity.

Just to refresh, a stationary time series is one whose characteristics like mean and variance does not change over time.

So, how to test for stationarity?

There is a suite of tests called unit-root tests. The popular ones are:

- 1. <u>Augmented Dickey-Fuller Test (ADF Test)</u> (<a href="https://www.machinelearningplus.com/time-series/augmented-dickey-fuller-test/">https://www.machinelearningplus.com/time-series/augmented-dickey-fuller-test/</a>)
- 2. <u>KPSS test (https://www.machinelearningplus.com/time-series/kpss-test-for-stationarity/)</u>
- 3. Philip-Perron test

Let's use the ADF test for our purpose.

By the way, if a series is found to be non-stationary, you make it stationary by differencing the series once and repeat the test again until it becomes stationary.

Since, differencing reduces the length of the series by 1 and since all the time series has to be of the same length, you need to difference all the series in the system if you choose to difference at all.

Got it?

Let's implement the ADF Test.

First, we implement a nice function (adfuller\_test()) that writes out the results of the ADF test for any given time series and implement this function on each series one-by-one.

```
def adfuller_test(series, signif=0.05, name="', verbose=False):
 """Perform ADFuller to test for Stationarity of given series and print report"""
 r = adfuller(series, autolag='AIC')
 output = \{'test\_statistic': round(r[0], 4), 'pvalue': round(r[1], 4), 'n\_lags': round(r[2], 4), 'n\_obs': r[3]\}
 p_value = output['pvalue']
 def adjust(val, length= 6): return str(val).ljust(length)
 # Print Summary
 print(f' Augmented Dickey-Fuller Test on "{name}"', "\n ", '-'*47)
 print(f' Null Hypothesis: Data has unit root. Non-Stationary.')
 print(f' Significance Level = {signif}')
 print(f' Test Statistic = {output["test_statistic"]}')
 print(f' No. Lags Chosen = {output["n_lags"]}')
 for key,val in r[4].items():
   print(f' Critical value {adjust(key)} = {round(val, 3)}')
 if p_value <= signif:</pre>
   print(f" => P-Value = {p_value}. Rejecting Null Hypothesis.")
   print(f" => Series is Stationary.")
   print(f" => P-Value = {p_value}. Weak evidence to reject the Null Hypothesis.")
   print(f" => Series is Non-Stationary.")
```

Call the adfuller\_test() on each series.

```
# ADF Test on each column

for name, column in df_train.iteritems():

adfuller_test(column, name=column.name)

print('\n')
```

Results:

```
Augmented Dickey-Fuller Test on "rgnp"

=> Series is Stationary.
```

After the first difference, Real Wages (Manufacturing) is still not stationary. It's critical value is between 5% and 10% significance level.

All of the series in the VAR model should have the same number of observations.

So, we are left with one of two choices.

That is, either proceed with 1st differenced series or difference all the series one more time.

```
# Second Differencing

df_differenced = df_differenced.diff().dropna()
```

Re-run ADF test again on each second differenced series.

#### # ADF Test on each column of 2nd Differences Dataframe

for name, column in df\_differenced.iteritems():
 adfuller\_test(column, name=column.name)
 print('\n')

Results:

Critical value 5% = -2.889
Critical value 10% = -2.581
=> P-Value = 0.0. Rejecting Null Hypothesis.
=> Series is Stationary.
```

All the series are now stationary.

Let's prepare the training and test datasets.

# 10. How to Select the Order (P) of VAR model

To select the right order of the VAR model, we iteratively fit increasing orders of VAR model and pick the order that gives a model with least AIC.

Though the usual practice is to look at the AIC, you can also check other best fit comparison estimates of BIC, FPE and HQIC.

```
model = VAR(df_differenced)

for i in [1,2,3,4,5,6,7,8,9]:

result = model.fit(i)

print('Lag Order =', i)

print('AIC : ', result.aic)

print('BIC : ', result.bic)

print('FPE : ', result.fpe)

print('HQIC: ', result.hqic, '\n')
```

Results:

#### Lag Order = 1

AIC: -1.3679402315450664
BIC: 0.3411847146588838
FPE: 0.2552682517347198
HQIC: -0.6741331335699554

#### Lag Order = 2

AIC: -1.621237394447824
BIC: 1.6249432095295848
FPE: 0.2011349437137139
HQIC: -0.3036288826795923

#### Lag Order = 3

AIC: -1.7658008387012791 BIC: 3.0345473163767833 FPE: 0.18125103746164364 HQIC: 0.18239143783963296

#### Lag Order = 4

AIC: -2.000735164470318 BIC: 4.3712151376540875 FPE: 0.15556966521481097 HQIC: 0.5849359332771069

#### Lag Order = 5

AIC: -1.9619535608363954
BIC: 5.9993645622420955
FPE: 0.18692794389114886
HQIC: 1.268206331178333

#### Lag Order = 6

AIC: -2.3303386524829053 BIC: 7.2384526890885805 FPE: 0.16380374017443664 HQIC: 1.5514371669548073

#### Lag Order = 7

AIC: -2.592331352347129 BIC: 8.602387254937796 FPE: 0.1823868583715414 HQIC: 1.9483069621146551

#### Lag Order = 8

AIC: -3.317261976458205 BIC: 9.52219581032303 FPE: 0.15573163248209088 HQIC: 1.8896071386220985

#### Lag Order = 9

AIC: -4.804763125958631 BIC: 9.698613139231597 FPE: 0.08421466682671915 HQIC: 1.0758291640834052

In the above output, the AIC drops to lowest at lag 4, then increases at lag 5 and then continuously drops further.

Let's go with the lag 4 model.

An alternate method to choose the order(p) of the VAR models is to use the model.select\_order(maxlags) method.

The selected order(p) is the order that gives the lowest 'AIC', 'BIC', 'FPE' and 'HQIC'

(https://www.machinelearningplus.com/wp-content/uploads/2019/07/VAR\_Order\_Selection\_Table-min.png)

According to FPE and HQIC, the optimal lag is observed at a lag order of 3.

I, however, don't have an explanation for why the observed AIC and BIC values differ when using result.aic versus as seen using  $model.select\_order()$ .

Since the explicitly computed AIC is the lowest at lag 4, I choose the selected order as 4.

# 11. Train the VAR Model of Selected Order(p)

model\_fitted = model.fit(4)
model\_fitted.summary()

Results:

# Summary of Regression Results ----Model: VAR

Method: OLS

Date: Sat, 18, May, 2019

# 12. Check for Serial Correlation of Residuals (Errors) using Durbin Watson Statistic

Serial correlation of residuals is used to check if there is any leftover pattern in the residuals (errors).

What does this mean to us?

If there is any correlation left in the residuals, then, there is some pattern in the time series that is still left to be explained by the model. In that case, the typical course of action is to either increase the order of the model or induce more predictors into the system or look for a different algorithm to model the time series.

So, checking for serial correlation is to ensure that the model is sufficiently able to explain the variances and patterns in the time series.

Alright, coming back to topic.

A common way of checking for serial correlation of errors can be measured using the Durbin Watson's Statistic.

(https://www.machinelearningplus.com/wp-content/uploads/2019/07/Durbin Watson Statistic Formula-min.png)

The value of this statistic can vary between 0 and 4. The closer it is to the value 2, then there is no significant serial correlation. The closer to 0, there is a positive serial correlation, and the closer it is to 4 implies negative serial correlation.

from statsmodels.stats.stattools import durbin\_watson
out = durbin\_watson(model\_fitted.resid)

for col, val in zip(df.columns, out):
 print(adjust(col), ':', round(val, 2))

```

The serial correlation seems quite alright. Let's proceed with the forecast.

# 13. How to Forecast VAR model using statsmodels

In order to forecast, the VAR model expects up to the lag order number of observations from the past data.

This is because, the terms in the VAR model are essentially the lags of the various time series in the dataset, so you need to provide it as many of the previous values as indicated by the lag order used by the model.

```
# Get the lag order
lag_order = model_fitted.k_ar
print(lag_order) #> 4

# Input data for forecasting
forecast_input = df_differenced.values[-lag_order:]
forecast_input
```

```
4
агтау([[ 13.5, 0.1, 1.4, 0.1, 0.1, -0.1, 0.4, -2. ],
[-23.6, 0.2, -2., -0.5, -0.1, -0.2, -0.3, -1.2],
[-3.3, 0.1, 3.1, 0.5, 0.3, 0.4, 0.9, 2.2],
[-3.9, 0.2, -2.1, -0.4, 0.2, -1.5, 0.9, -0.3]])
```

Let's forecast.

```
#Forecast
fc = model_fitted.forecast(y=forecast_input, steps=nobs)
df_forecast = pd.DataFrame(fc, index=df.index[-nobs:], columns=df.columns + '_2d')
df_forecast
```

The forecasts are generated but it is on the scale of the training data used by the model. So, to bring it back up to its original scale, you need to de-difference it as many times you had differenced the original input data.

In this case it is two times.

# 14. Invert the transformation to get the real forecast

```
def invert_transformation(df_train, df_forecast, second_diff=False):
    """Revert back the differencing to get the forecast to original scale."""

df_fc = df_forecast.copy()
    columns = df_train.columns

for col in columns:
    # Roll back 2nd Diff
    if second_diff:
        df_fc[str(col)+'_1d'] = (df_train[col].iloc[-1]-df_train[col].iloc[-2]) + df_fc[str(col)+'_2d'].cumsum()
    # Roll back 1st Diff
    df_fc[str(col)+'_forecast'] = df_train[col].iloc[-1] + df_fc[str(col)+'_1d'].cumsum()
    return df_fc
```

(https://www.machinelearningplus.com/wp-content/uploads/2019/07/VAR-Forecasts-min.png)

The forecasts are back to the original scale. Let's plot the forecasts against the actuals from test data.

# 15. Plot of Forecast vs Actuals

```
fig, axes = plt.subplots(nrows=int(len(df.columns)/2), ncols=2, dpi=150, figsize=(10,10))

for i, (col,ax) in enumerate(zip(df.columns, axes.flatten())):

df_results[col+'_forecast'].plot(legend=True, ax=ax).autoscale(axis='x',tight=True)

df_test[col][-nobs:].plot(legend=True, ax=ax);

ax.set_title(col + ": Forecast vs Actuals")

ax.xaxis.set_titcks_position('none')

ax.yaxis.set_titcks_position('none')

ax.spines["top"].set_alpha(0)

ax.tick_params(labelsize=6)

plt.tight_layout();
```

(https://www.machinelearningplus.com/wp-content/uploads/2019/07/forecast\_vs\_actuals\_VAR.png)

Forecast vs Actuals comparison of VAR model

# 16. Evaluate the Forecasts

To evaluate the forecasts, let's compute a comprehensive set of metrics, namely, the MAPE, ME, MAE, MPE, RMSE, corr and minmax.

```
from statsmodels.tsa.stattools import acf
def forecast_accuracy(forecast, actual):
  mape = np.mean(np.abs(forecast - actual)/np.abs(actual)) \ \# \textit{MAPE}
  me = np.mean(forecast - actual)
  mae = np.mean(np.abs(forecast - actual)) # MAE
  mpe = np.mean((forecast - actual)/actual) # MPE
  rmse = np.mean((forecast - actual)**2)**.5 \# RMSE
  corr = np.corrcoef(forecast, actual)[0,1] # corr
  mins = np.amin(np.hstack([forecast[:,None],
                  actual[:,None]]), axis=1)
  maxs = np.amax(np.hstack([forecast[:,None],
                  actual[:,None]]), axis=1)
  minmax = 1 - np.mean(mins/maxs)
                                             # minmax
  return({'mape':mape, 'me':me, 'mae': mae,
       'mpe': mpe, 'rmse':rmse, 'corr':corr, 'minmax':minmax})
print('Forecast Accuracy of: rgnp')
accuracy_prod = forecast_accuracy(df_results['rgnp_forecast'].values, df_test['rgnp'])
for k , v in accuracy_prod.items():
  print(adjust(k), ': ', round(v,4))
print('\nForecast Accuracy of: pgnp')
accuracy_prod = forecast_accuracy(df_results['pgnp_forecast'].values, df_test['pgnp'])
for k, v in accuracy_prod.items():
  print(adjust(k), ': ', round(v,4))
print('\nForecast Accuracy of: ulc')
accuracy_prod = forecast_accuracy(df_results['ulc_forecast'].values, df_test['ulc'])
for k, v in accuracy_prod.items():
  print(adjust(k), ': ', round(v,4))
print('\nForecast Accuracy of: gdfco')
accuracy_prod = forecast_accuracy(df_results['gdfco_forecast'].values, df_test['gdfco'])
for k, v in accuracy_prod.items():
  print(adjust(k), ': ', round(v,4))
print('\nForecast Accuracy of: gdf')
accuracy_prod = forecast_accuracy(df_results['gdf_forecast'].values, df_test['gdf'])
for k, v in accuracy_prod.items():

## 17. Conclusion

In this article we covered VAR from scratch beginning from the intuition behind it, interpreting the formula, causality tests, finding the optimal order of the VAR model, preparing the data for forecasting, build the model, checking for serial autocorrelation, inverting the transform to get the actual forecasts, plotting the results and computing the accuracy metrics.

Hope you enjoyed reading this as much as I did writing it. I will see you in the next one.

W Jing • 4 months ago

Thanks for sharing. Just wondering if you know how to get confidence interval of all the predicted values.

vishal sharma • 5 months ago

no explanation or use of cointegration test

des c ◦ 5 months ago

nice. I tried to run diff onced only, to see the error rate comparison with running diff twice, so i try to run df\_results = invert\_transformation(df\_train, df\_forecast, second\_diff=False), i get KeyError: 'rgnp\_1d' because the column isn't there, did i miss out anything?

Syed Rizvi • 5 months ago

Very helpful and detailed article! Just wanted to ask - Why you are not doing normalization/standardization here? If there is need for data normalization when do we need to do that?

Selva Prabhakaran Mod → Syed Rizvi • 5 months ago

Don't see harm in dong normalization, however by design it is not necessary. The weights get adjusted accordingly, so, if the scale of one of the series is too high, you still get fairly similar predictions

Michael Spacey • 6 months ago • edited

this is an incredibly detailed article. are you on Twitter? would love to follow. thanks!

Selva Prabhakaran Mod → Michael Spacey • 6 months ago

```
I run the @R_Programming handle.. Thanks for asking
```

Anatolijus • 8 months ago

Hi, thank you for the very interesting article. I see from the article that Granger's Causality test has been made before checking of stationarity of time series. Can we rely on the results of the such test?

Selva Prabhakaran Mod → Anatolijus • 6 months ago

The stationarity must be checked first. I overlooked this at the time of writing I'm afraid. Thanks for noticing this!

Chris • 10 months ago

If one wanted to test for seasonality how would one go about doing that?

```
^ | ✓ • Reply • Share ›
```

Selva Prabhakaran Mod → Chris • 10 months ago

Approved

Ary • 10 months ago • edited

Hello, thank you for your help. Why not do you check seasonality?

Selva Prabhakaran Mod → Ary • 6 months ago

It may be contributed by the participating series, if so, seasonality will be taken care of.

Moe • a year ago

Thanks for sharing this. this is very helpful to understand VAR. however, would you please explain what would be the change for multi-variate time series situation. I need to solve multivariate time series here. I have more than 8 columns/attributes for each of my time series.

thanks

Selva Prabhakaran Mod → Moe • 6 months ago

This example illustrates multivariate situation Moe. Not sure if I understood your question correctly

```

```

#### Suhas S Katte • a year ago

Hello , Thank you for this post . I have been trying to implement VAR time series on my own dataset which consists of two attributes . The ADF test results show that the series is stationary. The train dataset consists of 24000 values. The forecast values gives a constant value after a 100 predictions out of 9380 predictions being done, what could possibly be going wrong?

Selva Prabhakaran Mod → Suhas S Katte • 6 months ago

May be too much noise making the series harder to forecast.. can say for sure without looking at it

```
↑ | ∨ • Reply • Share >
```

Nick • a year ago • edited

Thanks for the excellent post.

I have a question regarding step 10. You say

According to FPE and HQIC, the optimal lag is observed at a lag order of 3

However, the output of

```
x = model.select_order(maxlags=12)
x.summary()
```

shows that the optimal lag order is 12 - this is where all 4 metrics (aic, bic, fpe, hqic) have their minima.

Why is there a discrepancy?

Selva Prabhakaran Mod → Nick • 6 months ago

I dont know the answer to the 'why'. I'm sorry. But what you could do is pick one per your intuition and see if the forecasts are good enough.

Amr Abdullah • a year ago

Hello, Thank you for this article. When I try to run step 14. I get the error "Train is not defined"

Shouldn't it be

df\_results = invert\_transformation(train\_df, df\_forecast, second\_diff=True)

not

df\_results = invert\_transformation(train, df\_forecast, second\_diff=True)

Thank you again

Selva Prabhakaran Mod → Amr Abdullah • 6 months ago

It's a typo. Thanks for noticing Amr

Kevin Kwong • a year ago

Hi. When I tried model.fit(0), error occur as below:

IndexError: index 0 is out of bounds for axis 0 with size 0

Do you know how to solve this?

Also, what is the "FALSE" in Cointegration Test mean? Is it mean that the data is not correlated to others?

Also, I have tried to test the model with other dataset. The result is quite poor. Is there any way to improve the accuracy?

Selva Prabhakaran Mod → Kevin Kwong • 6 months ago

'FALSE' could indicate the variables may not be inter-dependent to each other. Why would you want to fit a 0 model btw?

Nisar • a year ago

Hi,

As i observed in the grangers\_causality\_matrix

- 1) The p\_value: 0.0620 for gdfim\_x and rgnp\_y which is greater than significance. what does it mean? does it mean that gdfim\_x is not causing rgnp\_y if i am not wrong.
- 2) That matrix is not symmetric could you please explain which one is causing which one.

Selva Prabhakaran Mod → Nisar • 6 months ago

1) Probably perhaps
2) I've named the predictor with suffic '\_x' and dependent variable with suffix '\_y'

^ | ✓ • Reply • Share ›

Sirojiddin Nuriev • a year ago • edited

Hi.

I have time-series data 100000x20 (10 minutes). I am using LinearRegression(sklearn) model. My architecture looks like VAR model. but I don't need to do my data stationary. And I can use that model real-time as one-step-ahead forecasting. I should not retrain or refit.

Q1: is it VAR model?

Q2: what is the difference between my model and VAR?

Q3: Can I use VAR model for this data as real-time one-step ahead forecasting?

Please explain detail, thank you!

^ | ✓ • Reply • Share >

Selva Prabhakaran Mod → Sirojiddin Nuriev • 6 months ago

1) It is not a VAR model

- 2) In VAR model, all the participating series will influence each other both directions. The architecture of linear regression is not like that.
- 3. You may be able to perhaps, if it satisfies the above condition and the performance is fairly good.

^ | ✓ • Reply • Share ›

William Constantine • a year ago • edited

When I run the Granger causality code, as you defined it and using the same data, I get **all zeros** in the p-value matrix. Here is the run with verbose=True:

 $Y = pgnp, \; X = rgnp, \; P \; Values = [0.0, \; 1.0, \; 0.0$ 

In the definition of grangers\_causation\_matrix you have

min\_p\_value = np.min(p\_values)
df.loc[r, c] = min\_p\_value

which selects the minimum p-value for all lags tested and is the reason for my causality matrix to be filled

see more

^ | ✓ • Reply • Share >

Selva Prabhakaran Mod → William Constantine • 6 months ago

Thanks for sharing William. Apologize for the very late reply.

Gizem • a year ago

Hi

As i started to study for VAR, I realized this example has seasonality. So how do you handle with that ? I could not find good explanation about seasonality in VAR so can you please explain. Thank you!

^ | ✓ • Reply • Share ›

Selva Prabhakaran Mod → Gizem • a year ago • edited

Could you explain more about how you say there is seasonality?

VAR models the information contained only among the chosen group. Any seasonality modeled has to come from within this group

^ | ✓ • Reply • Share ›

suruchi • a year ago

I did not understand the invert function as why are you taking cumulative sum for the differenced series?

^ | ✓ • Reply • Share ›

Selva Prabhakaran Mod → suruchi • 6 months ago

the idea is to undo the differencing operations. Try reverse engineering it without the solution I've stated

^ | ✓ • Reply • Share ›

#### Wilson Mupfururirwa • a year ago

hi, I am trying to do vector autoregression model for a larger dataset than the one here. Mine has 10419 columns and 58 rows. I followed the procedure here and when running my model to show summary, it shows me this error: LinAlgError: 17-th leading minor of the array is not positive definite

l dont know how to solve this, please help me..

Selva Prabhakaran Mod → Wilson Mupfururirwa • a year ago

We need a reproducible example to be able to pinpoint whats happening. You might want to try and follow this thread: https://stackoverflow.com/q... to resolve this.

#### Alex Doffmam • a year ago

I'm fairly sure your method for testing Granger causality requires some diagnostics on whether the OLS in that function is well-specified.

Selva Prabhakaran Mod → Alex Doffmam • a year ago

Can you please elaborate on this?

**Alex Doffmam** ightharpoonup Selva Prabhakaran  $\circ$  a year ago  $\circ$  edited

If you look in the code base for the function grangercausalitytests, they apply statsmodels' OLS to compare the two series (with or without the x you test if Granger-cause y). So, as is common with OLS, one needs to check for iid errors etc.

Especially in time series, there's often autocorrelation.

Btw, there's also a built in test\_causality function inside the VAR class. But I just started working with statsmodels, so not sure yet what the difference is (besides what data it uses)

Salahadin Seid • a year ago

Thanks. This article helps me to understand VAR.

Selva Prabhakaran Mod → Salahadin Seid • a year ago

Adam Hurta • a vear ago

VAR model explained thoroughly and in a easy-to-understand fashion! Thank you!

Selva Prabhakaran Mod → Adam Hurta • a year ago

moar • a year ago

A very complete and thorough explanation on the topics. Thx!!

Selva Prabhakaran Mod → moar • a year ago
